of all medical education and is especially important when considering the cerebral vasculature, for which stroke is a defined risk for every endovascular procedure. Despite recent advances in noninvasive diagnostic neuroimaging, diagnostic cervicocerebral angiography remains the cornerstone and "gold standard" for the evaluation and treatment of patients with cerebrovascular disease (1). In addition to a high level of technical expertise, performance and interpretation of diagnostic cervicocerebral angiography requires in-depth cognitive knowledge of related neurological pathophysiology, neurovascular anatomy and pathology, and an understanding of the full range of neurodiagnostic possibilities. Expert diagnostic cervicocerebral angiography is the foundation for safe and successful cervicocerebral endovascular intervention, including carotid artery angioplasty and stenting for atherosclerosis, interventional stroke therapy, intracranial angio-

plasty and stenting, and embolization of cerebral aneurysms, epistaxis and vascular malformations. All of these procedures are increasing in volume and complexity with recent technological advances that further mandate the need for adequate cognitive acumen and technical skills. Formal neuroscience training and adequate procedural training and experience to achieve competency in diagnostic cervicocerebral angiography and interventional procedures, including carotid stenting, are essential to ensure proper outcomes. These concepts have been delineated in training requirements by the Accreditation Council for Graduate Medical Education (ACGME) and by previously published official society statements. The purpose of this document is to define the minimum training and experience necessary to provide adequate quality of patient care for extracranial cerebrovascular interventions, particularly carotid artery stenting. Hospital credentialing is

the mechanism by which competence is ensured.

RISKS OF CERVICOCEREBRAL ANGIOGRAPHIC PROCEDURES

Diagnostic Cervicocerebral Angiography

Stroke is recognized as the most disabling and costly of all medical conditions (2). Stroke is also the most feared of all iatrogenic medical and procedural complications. The risk of procedure-induced stroke may be a reason not to recommend the test for many physicians, and contributes to the reluctance of some patients to undergo the procedure (3–6). For medical and ethical reasons, any procedure that has “stroke” as a defined risk should be performed only by medical professionals with appropriate training and experience.

The risk of permanent neurological deficit as a result of diagnostic cerebral angiography is considerable and ranges from 0.3% to 5.7% (5,7–20). Experienced neurovascular specialists may have complication rates lower than 1% (20). There is additional risk of temporary neurological deficit ranging from 0.3% to 6.8% with, on average, a 2–3-fold increased risk of temporary as compared to permanent neurological deficit (7–20). Patients with atherosclerotic cerebrovascular disease as manifested by neurological symptoms (ipsilateral transient ischemic attack [TIA] or stroke) have a 2–3-fold higher risk of stroke from diagnostic cerebral angiography (0.5%–5.7% risk of permanent deficit) as compared to asymptomatic lesions (0.1%–1.2% risk) (5–10,15–20). In one study, 1,000 consecutive patients undergoing diagnostic cerebral angiography were assessed for procedure-related neurologic deficits (5). The overall stroke rate was 1%. However, nine of the 10 patients experiencing neurologic complications had a history of stroke or transient ischemic attack and the tenth had an “asymptomatic” bruit (5). Therefore, the highest level of practitioner training should be required for patients with prior symptoms, who are at highest risk for angiographic complications.

Operator experience as measured by decreased complications and de-

creased fluoroscopy time necessary for the examination improves in a linear fashion up to 100 cases (10). Analysis of the trainee learning curve suggests that 200 examinations are necessary for a physician to become a competent and secure examiner of the carotid and intracranial vasculature (10). Operator risk factors for angiographically produced ischemic complications (temporary and/or permanent stroke) are well known and include increased procedure and fluoroscopy time, increased number of catheters used, and performance of arch aortography (6–8). Performance of arch aortography may lead to greater numbers of emboli, thus leading to higher procedure complication rates than selective carotid angiography and is not infrequently performed by less well-trained practitioners (8,21). All of the aforementioned factors, including procedural time and multiple catheter use, are not independent and are typically related to inexperience and lack of specialized training in the cervicocerebral circulation (8,12). The effect of training and experience, and/or lack thereof, was clearly shown in a 5,000-angiogram analysis that demonstrated that fellowship-trained specialists have fewer neurologic complications (0.5%) than even experienced angiographers (0.6%), and both have far fewer complications than trainees under supervision (2.8%) (7,18,19). In the Asymptomatic Carotid Atherosclerosis Study (ACAS), the rate of stroke as a complication of diagnostic cerebral angiography was approximately 1.2% (17). This may be greater than the actual risk of stroke caused by the stenosis itself for many patients with asymptomatic stenosis (17). Indeed, this fact has led some vascular surgeons to suggest that diagnostic cervicocerebral angiography even when performed by well-trained neurovascular specialists may be too dangerous for the indication of asymptomatic carotid artery stenosis (22). However, more recent data has confirmed that the rate of stroke during routine diagnostic cerebral angiography when performed by appropriately trained and experienced neurovascular specialists is less than half the rate reported in ACAS (20).

Clinically obvious stroke may be the tip of the iceberg regarding complications of cervicocerebral angiography. “Silent” neuropathologic sequelae of cerebral embolism are even

more common than overt, clinically demonstrable neurologic complications (20,21,23–25). The fact that thromboembolic occurrences may be silent, yet still represent serious pathologic brain damage has recently been described in two magnetic resonance (MR) imaging studies in which diffusion-weighted pulse sequences ideal for detecting small infarcts were obtained after angiography (23,24). In one study, small new areas of brain infarction without overt clinical correlates were identified in 25% of 66 patients after diagnostic cerebral angiography (23). Detection of apparent embolic insults by MR imaging was more common in cases with longer fluoroscopic/procedural times ($P < .01$) and was associated with the use of multiple catheters ($P = .02$) (23). Both of these parameters have been shown to be associated with suboptimal training and experience (24). “Subclinical” infarcts have been shown to result in cognitive deficits on neuropsychologic testing after endarterectomy as well as carotid artery stenting (25). Similar procedural injury to the heart has been extensively documented secondary to coronary interventions by measurements of elevations in troponin levels (so-called troponin leak) and constitutes justification for the current stringent training standards for coronary intervention (26,27).

In addition to the technical risks of cerebrovascular procedures, there is also a risk of misdiagnosis if images are not interpreted correctly. This fact justifies formal and adequate cognitive training related to neurological and neurovascular anatomy, neurodiagnostic imaging, and neuro-pathophysiology. Physicians must be able to accurately identify stroke and TIA etiologies and evaluate traumatic and/or atherosclerotic neurovascular lesions and inflammatory conditions of the central nervous system. Evidence from numerous studies of coronary angiography performed by trained cardiologists demonstrates errors between observers’ assessments ranging from 15% to 45% for evaluating essentially only one variable, ischemic vascular disease (28). The ramifications of interobserver variation are considerable. If readings are erroneous, some patients will undergo interventional procedures unnecessarily, others might be denied an essential treatment, whereas

still other patients may have pathologic findings that are totally unrecognized (28). The implications of this degree of variability for patients with cerebrovascular conditions are significant when considering that physicians may be performing and interpreting cervicocerebral angiography outside of their primary specialty training and may then be performing interventions that have stroke as a defined potential risk. Even if cervicocerebral arteriography is performed solely for assessment of extracranial carotid occlusive disease, unexpected findings (vasculitis; congenital vascular malformations; tumors; mass effects; embolic complications; acute, subacute, or chronic dissection as opposed to atherosclerotic disease; aneurysms; arteriovenous fistulae; etc) require extensive neurodiagnostic and neuroangiographic knowledge and interpretive skills, which can only be obtained with appropriate formal training.

Cervicocerebral Interventional Procedures

Endovascular interventions carry a higher risk than diagnostic angiography in all vascular beds. The American College of Cardiology (ACC) has recognized this by requiring physicians to complete diagnostic coronary angiography training prior to beginning interventional coronary training (29). The risk of elective carotid stenting is greater than the risk associated with elective coronary intervention, which is typically less than 2% for emergency coronary artery bypass surgery and less than 2% for death (30,31). Randomized controlled trial data indicate stroke and death rates for carotid stenting ranging from 4.4% to over 12% at 30 days, with a 1-year stroke and death rate of up to 12% (32–41). MR imaging examinations demonstrate detectable ischemic lesions in 22%–29% of brains after carotid stenting (42,43). Additionally, a significant learning curve for carotid stenting has been clearly documented (44).

Potential benefit from “embolism protection” devices might render carotid stenting safer than is currently documented, but procedural stroke and death rates still range from at least 2.8% in one registry to over 6% at 30 days in other unpublished registries

for both asymptomatic and symptomatic patients (34,36,37,40). Indeed, in two randomized controlled trials comparing stent procedures with “protection” and with “no protection,” there was conflicting evidence concerning protection, with one trial indicating no difference and the other actually demonstrating worse outcomes “with protection” (45–47). Possible efficacy of “protection” devices has been demonstrated in at least one registry, in the carotid stenting arm of an endarterectomy versus stenting trial, and in a review article (40,48,49). Therefore, for carotid stenting, the conflicting proof of efficacy for protection devices, proved failure to eliminate all complications including stroke or death, and demonstrated patient risk greater than elective coronary intervention, for example, reaffirms that carotid stenting be performed only by individuals with sufficient cognitive neuroscience knowledge coupled with sufficient training and experience and subsequent excellent procedural technique, as described herein.

Cervicocerebral intervention not only includes carotid artery and extracranial angioplasty and stenting but also intracranial angioplasty and stenting as well as other therapies. The risks of neurological complications from intracranial angioplasty and stenting and cerebral aneurysm coiling are substantial. The reported neurologic complication rate for intracranial angioplasty and stenting ranges from 5% in 30 days to 36% (50–59). A significant learning curve has been demonstrated for coiling of cerebral aneurysms and the reported neurological complication rate ranges from 5% to 14% (60–64). Similar to the findings in carotid stenting, diffusion-weighted MR imaging reveals a higher rate of distal embolization associated with this procedure (up to 61%) than overt symptoms; many of the emboli are silent (21,23,24,65).

TRAINING

Official standards of training for all specialties have existed for over a quarter century; are the hallmark of medical licensure, board examinations and residency programs, individual physician privileges and hospital credentialing; and are recognized as vital by the Accreditation Council for Grad-

uate Medical Education (ACGME), the Federation of State Medical Boards of the United States, Inc., the American Board of Medical Specialties (ABMS), and the National Board of Medical Examiners (66–68). Furthermore, continuing assessment of competence is mandated by the Centers for Medicaid and Medicare Services as well as state medical licensing boards in the form of Continuing Medical Education (CME) credits (69–71). The Joint Commission on Approval for Healthcare Organizations (JCAHO) is working with two other accrediting organizations, the National Committee for Quality Assurance and URAC (formerly known as the Utilization Review Accreditation Commission), on coordinating and aligning patient safety standards (72–74). JCAHO has established guidelines for primary stroke centers based on Brain Attack Coalition recommendations that include quality of service standards for diagnostic cervicocerebral angiography (75). The Brain Attack Coalition has also established guidelines for Comprehensive Stroke Centers that mandate cognitive and technical neurovascular training and expertise to perform carotid stenting (Alberts MJ, Latchaw RE, Selman WR et al. Recommendations for Comprehensive Stroke Centers: A Consensus Statement from the Brain Attack Coalition. Submitted for publication).

Training guidelines for diagnostic arteriography and endovascular intervention are necessary for optimal and safe patient care and have been formulated and officially stated by numerous medical societies, including the American Heart Association (AHA), the ACC, the Society for Vascular Surgery (SVS), the Society of Interventional Radiology (SIR), the American Society of Neuroradiology (ASN), and American Society of Interventional and Therapeutic Neuroradiology (ASITN) (76–98). These AHA, ACC, SVS, SIR, ASNR, and ASITN guidelines mandate at least 100 diagnostic angiograms regardless of the vascular bed. The fact that there are varying degrees of difficulty for certain procedures and that these procedures thus impart associated degrees of risk to the patient has also been specifically recognized and summarized by the ACC (79). For example, in recognition of the critical nature of certain catheter

based procedures, the ACC has published the Revised Recommendations for Training in Adult Cardiovascular Medicine Core Cardiology Training II statement (COCATS 2) (29). In addition to the required minimum 24 clinical months of training by COCATS 2, diagnostic coronary catheterization mandates a minimum of 8 dedicated months in a cardiac catheterization laboratory during training in the pathophysiology and treatment of heart disease with specific requirements for approved supervised training on at least 300 diagnostic coronary angiograms before a practitioner is judged competent for credentialing purposes (29). This same concept is at least as important when dealing with the cerebral vasculature and the performance of cervicocerebral angiography.

The ACC has determined that cognitive training about the pathophysiology of the heart in addition to credentialing in diagnostic coronary angiography is a prerequisite for training in coronary intervention (80,84, 86,87). Furthermore, in addition to the core 24-month training period and 300 diagnostic coronary angiograms, the ACC recommends a full 20 months of supervised cardiac catheterization laboratory training with at least 250 supervised coronary stent procedures as the minimum acceptable requirements before a practitioner is judged competent to perform coronary interventions (88–92). The ABMS has not only affirmed that high degrees of training are necessary for appropriate and safe cardiac patient care but acknowledged this high level of achievement in the form of a Certificate of Added Qualification (CAQ) for Interventional Cardiology (99). These same principles are necessarily as crucial for the performance of interventional procedures relating to the cervicocerebral vasculature, including carotid stenting.

Existing Standards

Cognitive training in cerebrovascular disease.—The American Board of Radiology examinations for diagnostic radiology include written and oral subspecialty evaluation of neurodiagnostic imaging and neurologic and neurovascular anatomy and pathophysiology (100). This cognitive knowledge base includes stroke syn-

dromes and TIA etiologies, evaluation of traumatic and/or atherosclerotic neurovascular lesions, and inflammatory conditions of the central nervous system.

The range and complexity of neuroradiology, neurodiagnostic imaging, and cervicocerebral angiographic procedures is such that this has been recognized by the ABMS in the form of a CAQ in Diagnostic Neuroradiology (101). This training mandates a minimum of an entire additional year of formal ACGME-approved training beyond the radiology residency, and this knowledge is formally tested with an oral examination (101). This depth of knowledge and experience is unachievable in a casual or informal setting.

Due to the extensive body of knowledge in the medical discipline related to cervicocerebral pathophysiology and its clinical manifestations, an entire year beyond residency in neurology is required to achieve competence in vascular neurology. The complexity of this field of study of patients with cerebrovascular disease is further affirmed by the creation of the new ACGME-approved subspecialty of vascular neurology (102). Only after completing one year of vascular neurology training with additional training in neuroradiology can the neurology applicant enter into training in endovascular surgical neuroradiology (ESN) (103). The body of knowledge and skill obtained during the minimum of these 2 full years of additional dedicated formal postgraduate training after completion of a complete neurology residency are not achievable in a casual or informal setting.

Diagnostic cervicocerebral angiographic training.—The ACC and AHA recognize that adequate cognitive knowledge of the heart is a mandatory foundation for performance of coronary angiography and intervention and mandate 24 months as minimum cognitive training period (29). The clinical neuroscience societies herein, in agreement with the principles espoused by the ACC and AHA, believe that adequate cognitive knowledge of the brain is a mandatory foundation for performance of diagnostic cervicocerebral angiography and intervention. The cervicocerebral vasculature is technically de-

manding and clinically unforgiving and mandates competence in the performance of any procedures involving this vasculature. In recognition of this fact, the American Academy of Neurology has published guidelines for cervicocerebral angiography that recommend 100 appropriately supervised cervicocerebral angiograms as a minimum for required training and credentialing for this invasive procedure (95,96). Training and quality improvement guidelines for adult diagnostic cervicocerebral angiography have been officially formulated and published by the American College of Radiology, the ASITN, the ASNR, and the SIR (77,82). Radiology and its subspecialty neuroradiology were formerly the only medical specialties that incorporated cervicocerebral angiography into ACGME-approved residency training programs (101,104). Cervicocerebral angiography and intervention is now included in the new ACGME-approved endovascular surgical neuroradiology training program that includes physicians from neurosurgery, neurology, and neuroradiology (103).

Interventional cervicocerebral training.—The ACC, the AHA, and the SIR have published guidelines requiring 100 diagnostic angiograms for credentialing in *peripheral* vascular angioplasty (76,78–81). These AHA, ACC, and SIR standards mandate competence regardless of subspecialty background and/or endovascular experience in any other vascular bed, including the heart.

In recognition of the complexity and critical nature of interventional cervicocerebral procedures, the American Association of Neurological Surgery (AANS), the Congress of Neurological Surgeons (CNS), the AANS/CNS Cerebrovascular Section, the ASITN, and the ASNR published a unanimously endorsed statement specifying training requirements for the safe endovascular treatment of conditions that affect the brain, including the procedure of carotid stenting (97). These *Program Requirements for Residency/Fellowship Education in Neuroendovascular Surgery/Interventional Neuroradiology: A Special Report on Graduate Medical Education* mandate 100 diagnostic cervicocerebral angiograms prior to training in

this neurointerventional specialty, similar to the mandated requirements of COCATS 2 (29). This requirement is not altered by prior angiographic experience in any other vascular territories.

The ACGME has given its highest form of recognition for the need for advanced training for endovascular interventions involving the cervicocerebral and intracranial vasculature by officially recognizing the new discipline of endovascular surgical neuroradiology (103). The complexity of this medical/surgical discipline requires a minimum total of 7–8 years of dedicated formal postgraduate cognitive and procedural training with qualified supervision: far longer than most specialties. Appropriately prepared neurologists, neurosurgeons, and neuroradiologists are eligible to enter this ACGME training program. This ACGME-approved ESN training program explicitly incorporates additional training in clinical neurointensive care, as well as thorough training in advanced endovascular neuroradiologic procedural techniques (103). The ACGME-defined program of ESN specifically elucidates training in the indications, contraindications and technical aspects of carotid stenting for atherosclerosis (103).

Knowledge Necessary for Cerebrovascular Intervention

Our collaborative neuroscience societies, in agreement with the principles espoused in the ACC COCATS 2, recognize the necessity of three components of adequate training for competency to perform cervicocerebral diagnostic and interventional procedures: (i) formal training which imparts an adequate depth of cognitive knowledge of the brain and its associated pathophysiologic vascular processes, including management of complications of endovascular procedures, (ii) adequate procedural skill achieved by repetitive supervised training in an approved clinical setting by a qualified instructor, and (iii) diagnostic and therapeutic acumen, including the ability to recognize and manage procedural complications, achieved by studying, performing and correctly interpreting a large number of diagnostic procedures with proper tutelage.

Just as with diagnostic coronary angiography and coronary intervention, extensive knowledge of the brain and the ability to correctly *interpret* a cervicocerebral angiogram is the prerequisite and foundation for the *technical performance* of cervicocerebral angiography. The ability to adequately assess the array of diagnostic imaging studies of the brain with adequate knowledge of the numerous pathophysiologic possibilities is a necessary attribute of any practitioner who would perform cervicocerebral procedures, irrespective of the primary specialty of the practitioner.

Although interpretative skills of imaging are essential, clinical cognitive skills related to the epidemiology, diagnosis, and management of patients with cervicocerebral vascular disorders are the sine qua non of quality patient care, safety, and treatment selection. All major industry and National Institutes of Health (NIH)-sponsored trials related to carotid stenting and cervicocerebral interventions, including asymptomatic, symptomatic and high surgical risk patients, have required an independent assessment by a board-certified neurologist. This assessment includes documented competency in performing a complete neurological evaluation including the NIH Stroke Scale. Consequently, we not only endorse this principle in general practice, but also mandate adequate training for all neuroendovascular practitioners that encompasses knowledge of stroke syndromes and includes formal training and competency in the NIH Stroke Scale.

Competence in recognizing any procedural complication and being able to offer the most appropriate treatment is one of the basic goals of adequate formal training, particularly concerning cervicocerebral angiography and/or intervention. This would include the ability to recognize clinical intra- or postprocedural neurological symptoms as well as pertinent angiographic findings and the proper cognitive and technical skills to offer the most appropriate therapy. While this therapy might entail intracranial endovascular rescue, it might also entail optimal hemodynamic management necessitating sufficient clinical neurointensive skills.

Our collaborative neuroscience so-

cieties recognize that practitioners from a variety of backgrounds may currently have or wish to develop endovascular skills. Our consensus is that a minimum amount of formal cognitive training specifically related to stroke and cerebrovascular disease is essential for any physician to perform diagnostic cervicocerebral angiography and interventional procedures. Therefore, in addition to procedural technical experience requirements, a minimum of 6 months of formal cognitive neuroscience training in an ACGME-approved training program in radiology, neuroradiology, neurosurgery, neurology, and/or vascular neurology is required. This minimum formal training applies to all practitioners who wish to be credentialed to perform diagnostic cervicocerebral angiography and/or cervical carotid interventions, including practitioners from specialties with or without dedicated training in clinical neuroscience as part of their ACGME-approved residency programs.

Augmentation of Training

Simulator training has been shown to be of benefit in limited medical applications (105–112). At the present time, appropriate formal training and experience in clinical cervicocerebral angiography and intervention in an approved clinical training program has no adequate substitute in contemporary medical practice, but future trainees may benefit from added training on medical simulators. At the present time, simulator equipment is neither perfected nor validated for training purposes concerning the cervicocerebral vasculature, but it is anticipated that eventually these technologies may offer up to, but not greater than, 20% of the required training experience in procedural technique. Our collaborative societies, consistent with ACGME training standards and the ACC training standards (COCATS 2), emphasize that industry-sponsored seminars, CME coursework, and self-taught learning are insufficient for credentialing related to diagnostic cervicocerebral angiography, extracranial interventions, intracranial interventions, or carotid stenting.

Maintenance and Assurance of Continuing Quality of Care

Procedures that have stroke as a defined potential risk require the highest level of competency. Proficiency is maintained by lifelong continuing medical education as well as continuing performance of cases with adequate success and outcomes with minimal complications. Quality assurance and continuing improvement are necessary for high quality health care regardless of which discipline might be involved in treating patients. The quality improvement process is a patient oriented process, designed to ensure a baseline level of quality and predictable outcomes, and represents in many ways a safety net for the credentialing process. A post-hoc quality assurance process is no substitute for adequate and appropriate physician training leading to acceptably skilled practitioners suitable for credentialing. A quality assurance process should confirm that procedures are performed for appropriate indications with rates of success and complications that meet acceptable standards. Such quality improvement standards have been published for diagnostic cerebral angiography as well as extracranial carotid stenting (77,82,95,113). Such standards are necessary for quality assurance for procedures of such considerable consequence. The outcomes required by these standards should be achieved both during the training cases and following granting of credentials to ensure maintenance of competence. At this time there is insufficient information to know if maintenance of competency requires annual performance of specific numbers of cases, but data from other vascular interventional procedures such as coronary stenting, coronary artery bypass grafting, and carotid endarterectomy indicate that, in general, greater experience confers better outcomes (114–116).

CONSENSUS OF THE COLLABORATING NEUROSCIENCE SOCIETIES

1. All collaborating neuroscience societies are of the unanimous opinion that the safety of the patient is paramount.
2. Defined formal training and experience in *both* the cognitive *and* technical aspects of the neurosciences are essential for the performance and interpretation of diagnostic and therapeutic cervical and cerebrovascular procedures. Therefore, in addition to procedural technical experience requirements, a minimum of 6 months of formal cognitive neuroscience training is required in an approved program in radiology, neuroradiology, neurosurgery, neurology, and/or vascular neurology for any practitioner performing cervical carotid interventional therapy, including carotid stenting. This minimum neuroscience training recommendation applies to all practitioners, whether from specialties with or without dedicated training in the clinical neurosciences as part of their ACGME-approved residency programs.
3. All collaborating neuroscience societies endorse the principles of the several published standards from our various societies for training and quality concerning cervicocerebral angiography and intervention (77,82,95–97,113). We affirm the necessity for adequate and appropriate cognitive knowledge as well as adequate specialized procedural training and experience as described herein for credentialing in cervicocerebral angiography. Credentialing to perform (and in some cases interpret) cervicocerebral angiograms for one single purpose (eg, evaluation of carotid occlusive disease) theoretically approves performance and interpretation for all purposes or neurovascular conditions without distinction, some of which (eg, cerebrovascular trauma, vasculitis, congenital vascular malformations, tumors, mass effects, identification of embolic complications, differentiation of acute/subacute/chronic dissection from atherosclerotic disease, diagnosis of arteritides, identification of intracerebral aneurysms, etc) clearly demand interpretive skills not conferred by casual training and experience. Therefore, limited credentialing for limited procedures with limited training is unacceptable.
4. All collaborating neuroscience societies recommend appropriately supervised cervicocerebral angiography training and resultant credentialing with an accumulated total of 100 diagnostic cervicocerebral angiograms *before* postgraduate training in cervicocerebral interventional procedures, including carotid stenting, as described herein (29,97).
5. All collaborating neuroscience societies endorse the principles of training and quality assurance espoused in the multisociety *Quality Improvement Guidelines for the Performance of Carotid Angioplasty and Stent Placement* (113), which include a defined training pathway for any qualified practitioner for carotid stent training.
6. All collaborating neuroscience societies specifically endorse the principles of the ACGME and the training programs in endovascular surgical neuroradiology (103), vascular neurology (102) and neuroradiology (101).

CONCLUSIONS

All medical societies directly or indirectly involved with cervicocerebral angiography concur in the necessity of quality and safety of patient care. Credentials committees at each hospital and institution must promote adequate standards of training and experience for initial accreditation in diagnostic cervicocerebral angiography that are uniform across all specialties, guarantee patient safety, and assure continuous high quality of performance. Furthermore, credentials committees should certify and enforce prospective quality improvement programs that are consistent with mandated and accepted training standards as defined by the ACGME, the American Medical Association, the ABMS, and individual state medical licensing boards. Credentials committees are expected to guarantee that individual physicians diagnosing and treating cerebrovascular disease with endovascular procedures have sufficient formal neuroscience training and experience as well as adequate training in the performance and interpretation of diagnostic cervicocerebral an-

giography and the implications of the varied potential findings so as to optimize the proper expected medical outcomes and assure patient safety. Due to the grave consequences of inadequate or deficient training, stringent credentialing criteria with formal neuroscience training as specified by published standards and as elucidated herein should be mandated for those performing carotid, vertebral, and intracranial cerebrovascular interventions, just as is the case with coronary interventions (83–94,97,113).

APPENDIX 1: NEUROVASCULAR COALITION WRITING GROUP

The following individuals served as authors/reviewers of the NeuroVascular Coalition Writing Group: John J. Connors, III, MD (ASITN), Miami Cardiac & Vascular Institute, Baptist Hospital of Miami, Miami, FL; David Sacks, MD (SIR), The Reading Hospital and Medical Center, West Reading, PA; Anthony J. Furlan, MD (AAN), Cerebrovascular Center, The Cleveland Clinic Foundation; Warren R. Selman, MD (AANS), Department of Neurosurgery, Case Western Reserve University School of Medicine, Cleveland, OH; Eric J. Russell, MD (ASNR), Department of Radiology, Northwestern University, Chicago, IL; Philip E. Stieg, MD, PhD (AANS/CNS Cerebrovascular Section), Department of Neurological Surgery, New York Presbyterian Hospital, New York, NY; Mark N. Hadley, MD (CNS), University of Alabama Division of Neurosurgery, Birmingham, AL; Joan C. Wojak, MD (ASITN), Neuroscience Center, Our Lady of Lourdes Regional Medical Center, Lafayette, LA; Walter J. Koroshetz, MD (AAN), Neurosurgery, Massachusetts General Hospital, Boston, MA; Roberto C. Heros, MD (AANS), Department of Neurological Surgery, University of Miami School of Medicine, Miami, FL; Charles M. Strother, MD (ASNR), Neuroradiology, The Methodist Hospital, Houston, TX; Gary R. Duckwiler, MD (ASITN), Department of Radiology, UCLA School of Medicine, Los Angeles, CA; Janette D. Durham, MD, MBA (SIR), Department of Radiology, University of Colorado Health Sciences Center, Denver, CO; Thomas O. Tom-sick, MD (ASNR), Radiology Depart-

ment, University of Cincinnati, Cincinnati, OH; Robert H. Rosenwasser, MD, FACS (AANS/CNS Cerebrovascular Section), Department of Neurosurgery, Division of Cerebrovascular Surgery and Interventional Neuroradiology, Thomas Jefferson University Hospital, Philadelphia, PA; Cameron G. McDougall, MD (ASITN), Barrow Neurological Institute, Phoenix, AZ; Victor M. Haughton, MD (ASNR), Department of Radiology, University of Wisconsin Hospital and Clinics, Madison, WI; Colin P. Derdeyn, MD (ASITN), Mallinckrodt Institute of Radiology and the Departments of Neurology and Neurological Surgery, Washington University School of Medicine, St. Louis, MO; Lawrence R. Wechsler, MD (AAN), Stroke Institute, Presbyterian University Hospital, UPMC Stroke Institute, Pittsburgh, PA; Patricia A. Hudgins, MD (ASNR), Neuroradiology, Emory University School of Medicine; Mark J. Alberts, MD (AAN), Department of Neurology, Northwestern University Medical School, Chicago, IL; Rodney D. Raabe, MD (SIR), Department of Radiology, Sacred Heart Medical Center, Spokane, WA; Camillo R. Gomez, MD (AAN), Alabama Neurological Institute, Birmingham, AL; C. Michael Cawley, III, MD (CNS), The Emory Clinic/Neurosurgery, Atlanta, GA; Katharine L. Krol, MD (SIR), Vascular and Interventional Radiology, Indianapolis, IN; Nancy Futrell, MD (AAN), Intermountain Stroke Center, Salt Lake City, UT; Robert A. Hauser, MD, MBA (AAN), Neurology, The Harborside Medical Tower, Tampa, FL; and Jeffrey I. Frank, MD, FAAN, FAHA (AAN), Department of Neurology, The University of Chicago, Chicago, IL.
